

# $\text{CFH}_2\text{CF}_3$ (HFC-134a) Pseudo-Line-List

Geoff Toon  
Jet Propulsion Laboratory  
2018-05-16

Six data-sets of laboratory spectra, downloaded from the HITRAN website, have been used to generate an empirical pseudo-linelist. Transmission spectra, generated from the lab cross-section data, were fitted simultaneously in order to minimize residuals between the lab spectra and synthetic spectra calculated from the PLL. In some spectral regions up to 70 spectra were used.

# Available Laboratory Spectra

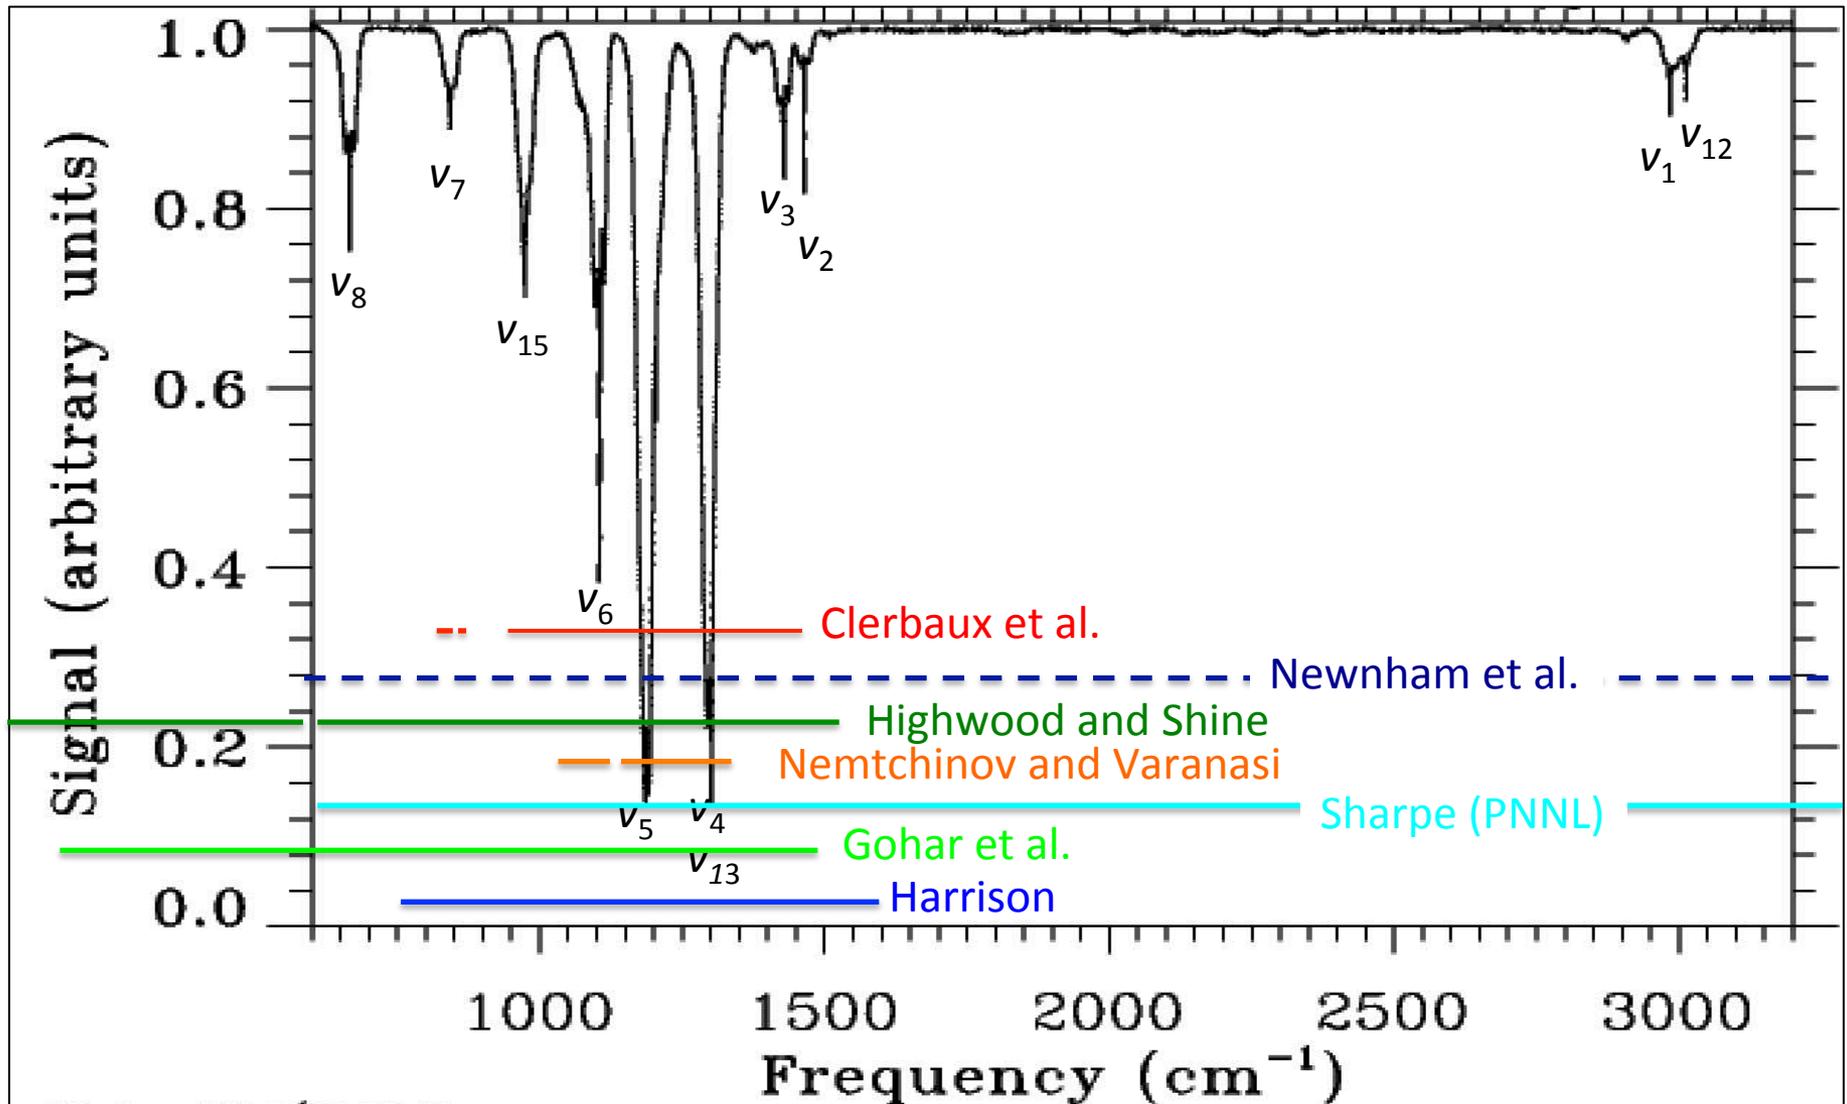

Seven different  $\text{CFH}_2\text{CF}_3$  spectral datasets have been measured. Six of these were downloaded from the HITRAN website and used to derive the PLL. Preference was given to those in the supplemental folder, where the -ve absorption coefficients have not been zeroed.

#	Reference	Range (cm <sup>-1</sup> )	Temp (K)	Pres (Torr)	Applied Scaling	N <sub>s</sub>
A	Clerbaux et al. [1993]	815- 865 935-1484	253-287		0.72	0/3 3/3
B	Newnham et al. [1996]	600-3500	203-294	38-760	-	0/3

E	Sharpe et al. [2004]	600-5000	278-323	760	1.00	3/3
F	Gohar et al. [2004]	300-1550	296	700	0.95	1/1
G	Harrison [2015]	750-1600	191-296	24-760	1.00	27/27

## Footnotes:

1. Newnham et al. are included in the table for completeness; the spectra are missing from the HITRAN website and were therefore not used in the derivation of the PLL.
2. Only 32½ of 49 tabulated Nemtchinov spectra are available from HITRAN: all the lowest-P spectra at each temperature are missing, as are the all the lowest-T (180K) spectra.
3. The Clerbaux's spectra covering 815-865 cm<sup>-1</sup> were too narrow and too noisy to be useful.

# Sharpe et al. (PNNL) 278K spectrum

Illustrating main absorption bands of  $\text{CF}_2\text{HCF}_3$  and the coverage of the laboratory spectra

# Twelve Fitted Windows

Defined 12 windows, each centered on an absorption band. Chose each window based on three criteria:

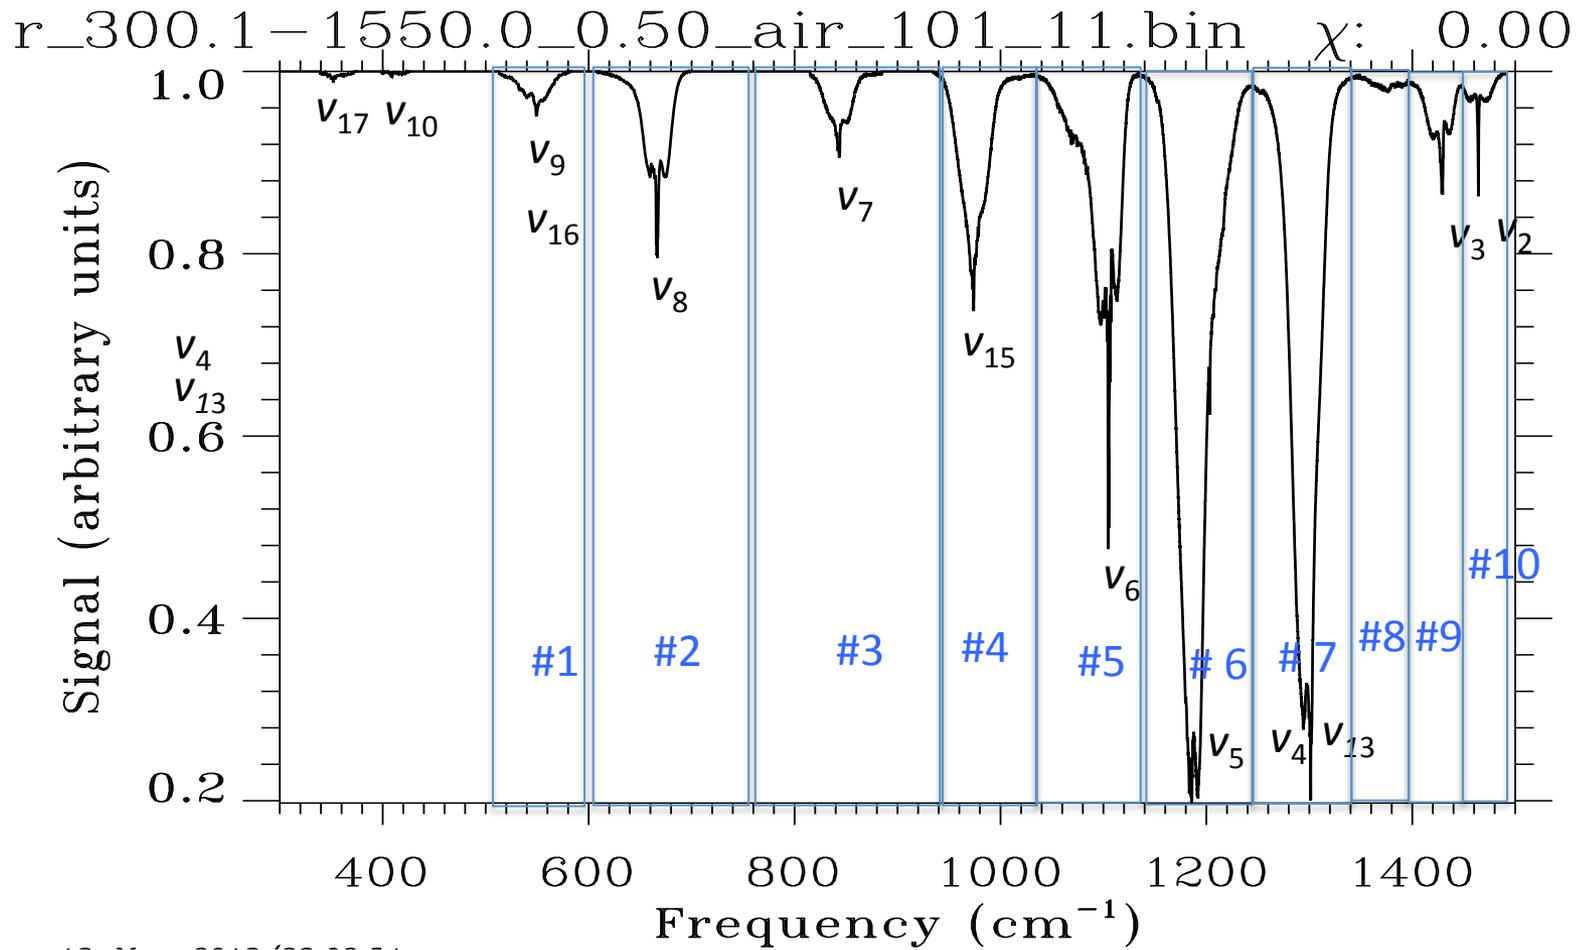

- 1) Boundaries in regions of weak absorption
- 2) Maximize utilization of the various datasets
- 3) Maximize spectral coverage

The right-most column ( $N_s$ ) shows the total number of spectra that were fitted in each window. In total 412 spectral fits were performed out of a potential  $103 \times 12 = 1236$

Although there are absorption bands visible below  $500 \text{ cm}^{-1}$  in the spectrum of Highwood and Shine, these are substantially weaker than the  $\nu_9$  band centered at  $549 \text{ cm}^{-1}$ . Based on their weakness and the very limited lab spectra, it was decided not to extend the PLL below  $500 \text{ cm}^{-1}$

# Partition Function

For the vibrational partition function, the following 18 modes were used with the tabulated wavenumbers and degeneracies:

$\nu_1$	: 2981	1
$\nu_2$	: 1462	1
$\nu_3$	: 1428	1
$\nu_4$	: 1301	1
$\nu_5$	: 1185	1
$\nu_6$	: 1104	1
$\nu_7$	: 843	1
$\nu_8$	: 666	1
$\nu_9$	: 549	1
$\nu_{10}$	: 408	1
$\nu_{11}$	: 225	1
$\nu_{12}$	: 3010	1
$\nu_{13}$	: 1294	1
$\nu_{14}$	: 1191	1
$\nu_{15}$	: 973	1
$\nu_{16}$	: 540	1
$\nu_{17}$	: 358	1
$\nu_{18}$	: 110	1

A molecular weight of 102 was used.

A rotational partition function of  $(296/T)^{1.5}$

A residual T-dependence of 5% was implemented.

These values are based on the paper on the following page.

# Removal of Biases

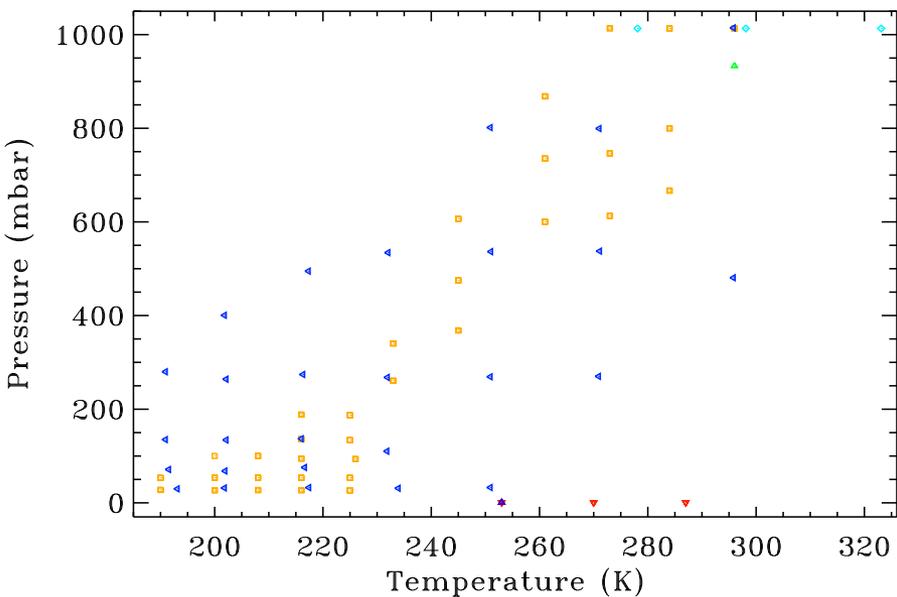

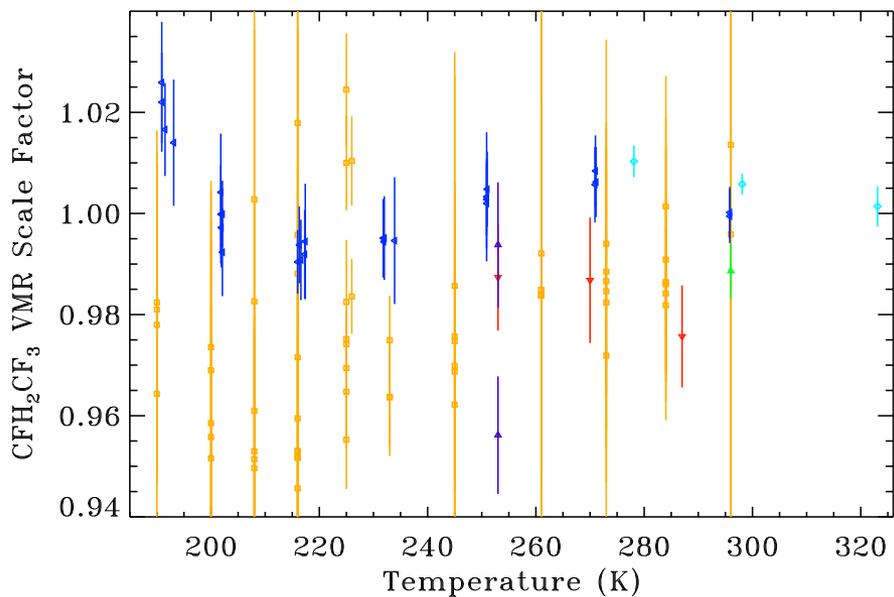

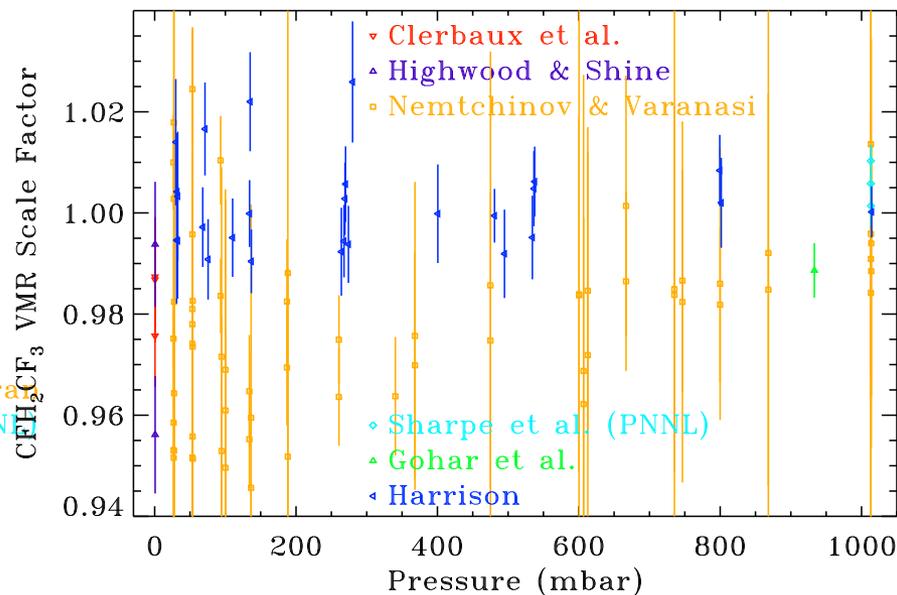

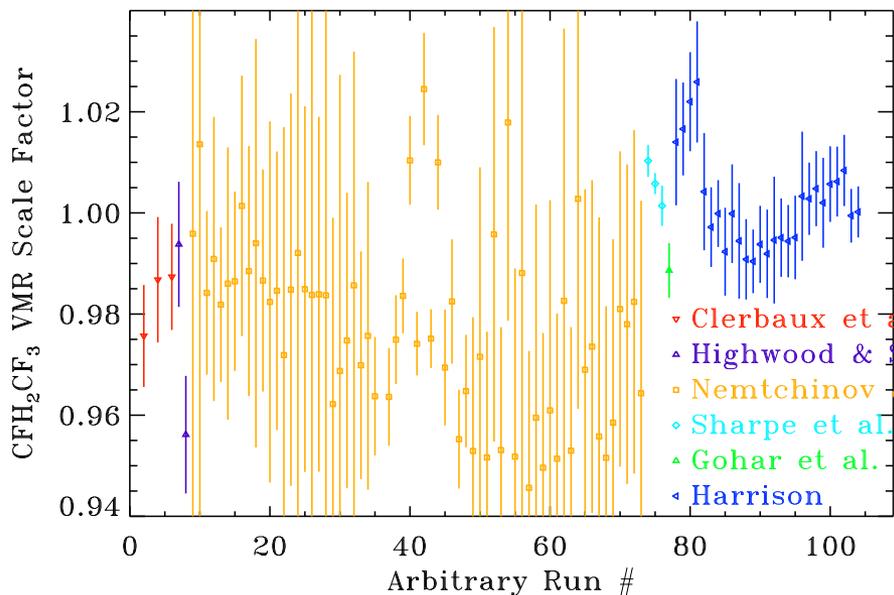

It is important that all the various spectra are brought into consistency, in terms of the absolute absorption cross-section and wavenumber calibrations, before a PLL is generated. Otherwise the biases will generate artifacts in the PLL parameters due to the different coverage (in terms of temperature, pressure, wavenumber) of the different data-sets.

For example, if a data-set that was acquired only at low temperatures were biased low in terms of the absorption cross-sections, this would lead to a high bias in the overall derived  $E''$  values in the spectral regions covered by this erroneous data-set.

For this reason, there were adjustments made to the Clerbaux and Gohar cross-sections. The former were multiplied by 0.72 and the latter by 0.95 before use in deriving the PLL. The other four data-sets seems to be consistent within 5%.

Subsequent plots show results **after** applying corrections to the cross sections and the wavenumber calibration.

# Retrieved CFH<sub>2</sub>CF<sub>3</sub> amounts (VSFs)

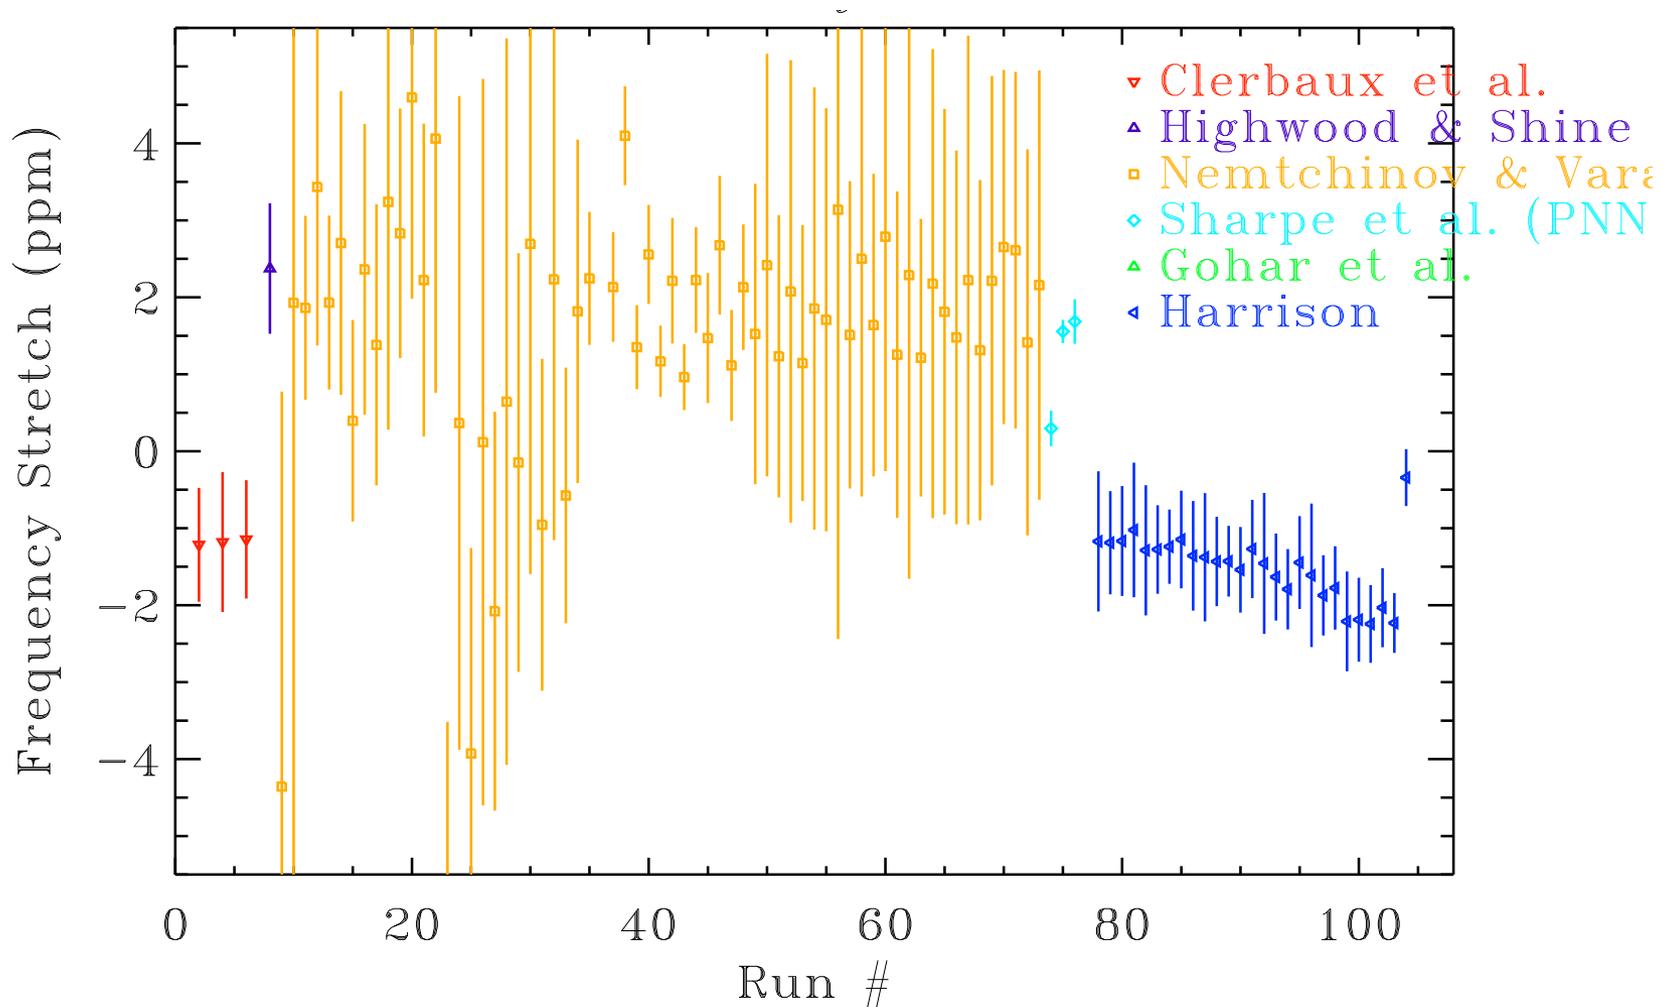

# Discussion

Previous slide shows retrieved  $\text{CFH}_2\text{CF}_3$  amounts, relative to the actual amount based on the measurement conditions, scaled by the correction factors on slide 2 (0.72 for Clerbaux et al., 0.95 for Gohar, and 1.0 for the others). These VMR Scale Factors (VSFs) would all be 1.0 in a perfect world. Data from all available windows are averaged for each spectrum, reducing the dimensionality of the problem, avoiding having 12 very similar plots – one for each window.

Retrieved  $\text{CFH}_2\text{CF}_3$  amounts are generally consistent amongst measurements, with the exception of the Clerbaux data, which produce only 72% of the true gas amount, implying that the Clerbaux cross-sections are too large.

Curvature in the T-dependence of the VMR scale factors was observed to be  $\pm 5\%$  with a minimum at 250K was also corrected by application of an extra correction factor. This correction had already been applied in the previous plot. This curvature is very likely to be due to hot-bands of significant strength underlying the fundamentals, which invalidate the basic assumption that a single line can represent the absorption at each wavenumber.

# Retrieved Frequency Stretches (ppm)

A wavenumber stretch of 2 ppm corresponds to  $0.002 \text{ cm}^{-1}$  at  $1000 \text{ cm}^{-1}$

# Summary

Six different lab spectral datasets of  $\text{CFH}_2\text{CF}_3$  absorption have been fitted simultaneously to generate a single PLL to represent their absorption.

103 spectra were fitted over 12 different windows. Out of the 1236 potential spectral fits, only 412 could actually be performed. This was mainly due to the limited coverage of many spectra and a few data quality issues.

The resulting pseudo-linelist contains:

- 209,201 lines covering 504-1550  $\text{cm}^{-1}$  at 0.005  $\text{cm}^{-1}$  spacing
- 26,001 lines covering 2790-3050  $\text{cm}^{-1}$  at 0.010  $\text{cm}^{-1}$  spacing

235,202 total lines

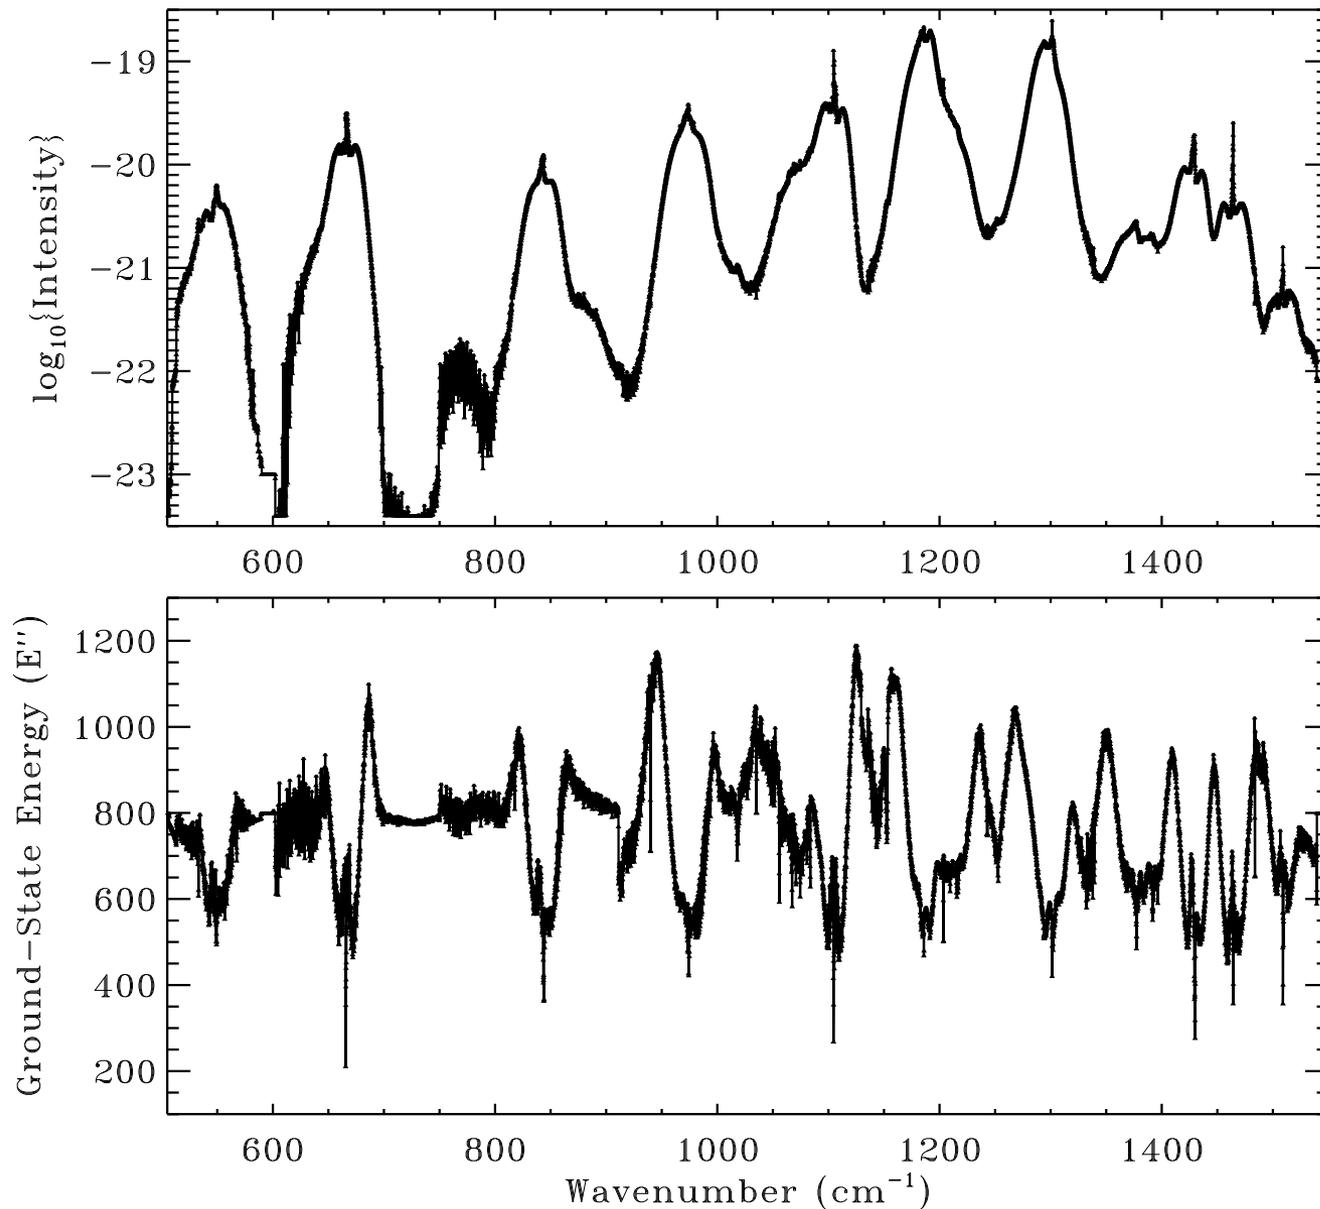

The linelist uses the old HITRAN 2000 format with 100 characters per line.

Gas # 76 was arbitrarily assigned to  $\text{CFH}_2\text{CF}_3$  with isotopolog #0. The former can be changed.

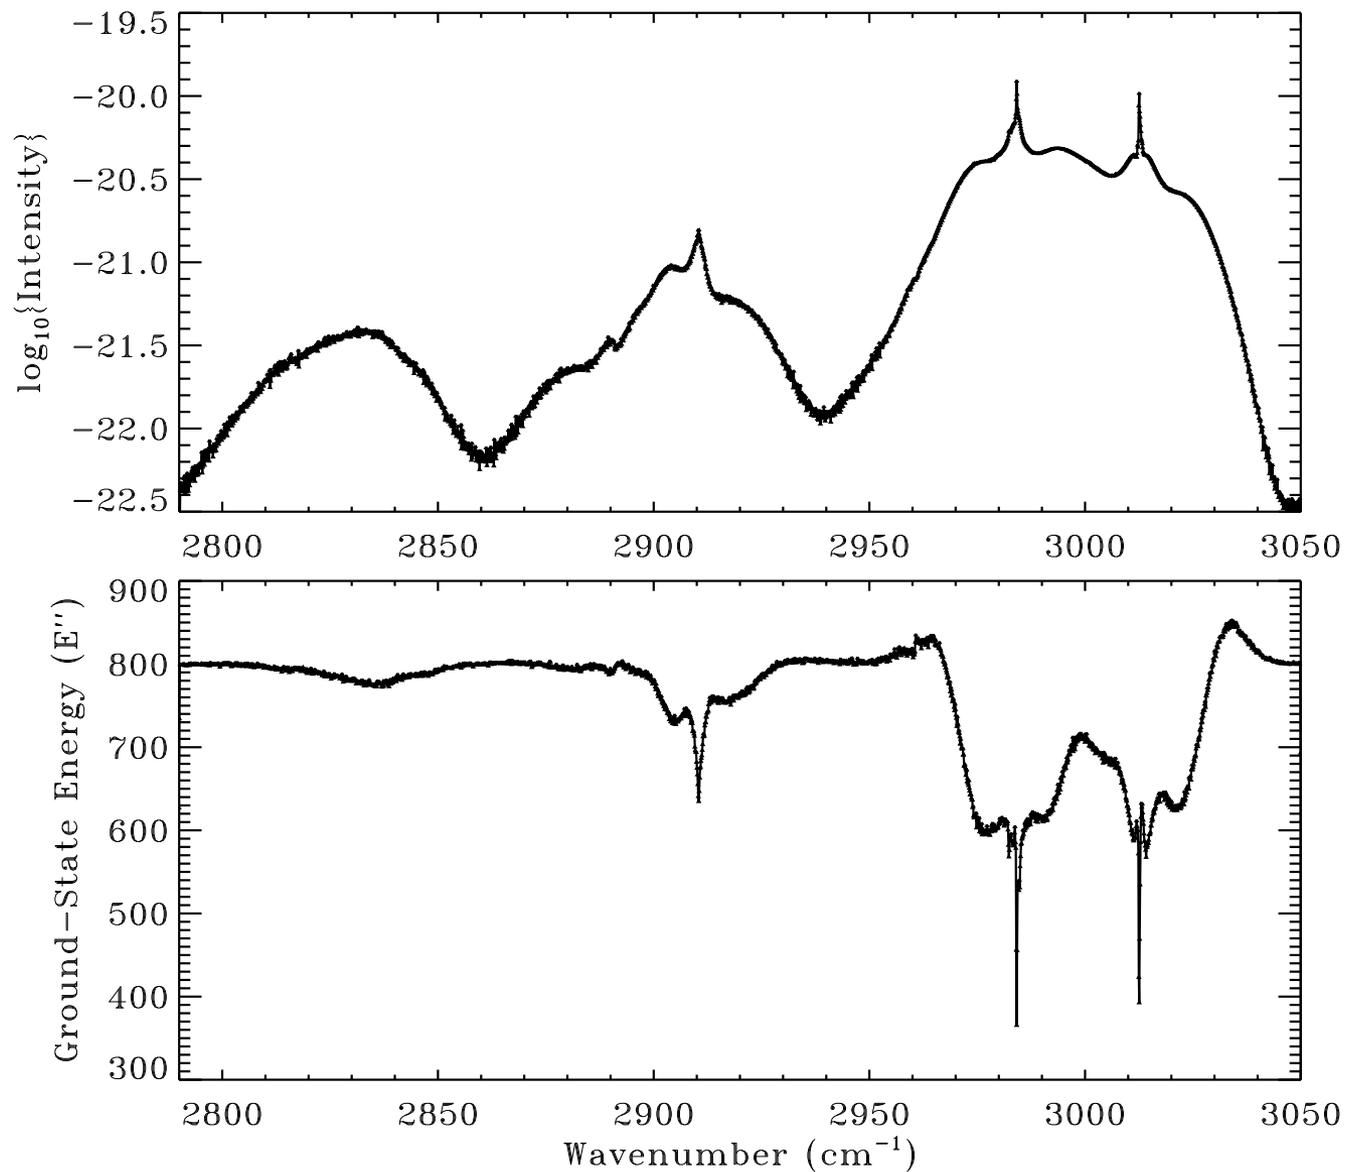

# Future Work

- 1) Get hold of the Newnham et al. cross-sections and include in a future –re-analysis.
- 2) Try to find missing Nemtchinov & Varanasi spectra and include in a future re-analysis.
- 3) Although the Gohar et al. spectral cross-sections start at  $300\text{ cm}^{-1}$ , they are actually all zero up to  $339\text{ cm}^{-1}$ . Similarly, although the Gohar spectrum nominally extends to  $1550\text{ cm}^{-1}$ , beyond  $1490\text{ cm}^{-1}$  it is all zeros. There are also zeros between all the bands including the  $374\text{-}399$  and  $426\text{-}513\text{ cm}^{-1}$  regions. The latter causes a problem because the PLL starts at  $504\text{ cm}^{-1}$ . GFIT assumes that the Gohar cross-section is really zero below  $513\text{ cm}^{-1}$ , which biases the PLL strengths low and creates artifacts in the derived  $E''$  and curvature.  
  
Not sure of the origin of these zeros. Perhaps the cross-sections went negative and were set to zero. So It might be better to chop up the Gohar spectrum into multiple slices with non-zero cross-sections, discarding the regions where the cross-sections are zero. This way, GFIT won't be able to fit the zeroed regions, preventing biasing the PLL intensities.
- 4) Although the Highwood & Shine absorption spectrum nominally covers  $600\text{-}1540\text{ cm}^{-1}$ , it is actually zero between  $700\text{-}753\text{ cm}^{-1}$ ,  $913\text{-}942\text{ cm}^{-1}$  and other places.
- 5) Investigate noisy patch in Intensities and  $E''$  from  $650\text{-}700\text{ cm}^{-1}$ . Is it simply a lack of noise above  $700\text{ cm}^{-1}$  due to the Highwood & Shine cross-sections being set to zero there?
